

Observational comparison, not a controlled ablation. Loss was one of nine hyperparameters drawn independently in the 40-trial random search, so BCE and focal trials also differ in learning rate, dropout, hidden dimension and batch size; the difference between the two boxes cannot be attributed to the loss alone. Each point is one trial (single run, no seed replication). A controlled ablation would hold every other hyperparameter at the selected configuration and vary only the loss. Generated by `src/plot_reviewer_figures.py` from `plots/arc_tuning_cafa/trial_metrics.csv`.
